SPACE IS THE PLACE: THE LAWS OF FORM AND SOCIAL SYSTEMS

Michael Schiltz

ABSTRACT: It is well known that **Niklas Luhmann's theory of social systems is grounded in Spencer-Brown's seminal *Laws of Form (LoF)* or 'calculus of indications'**. It is also known that the reception of the latter has been rather problematic. This article attempts to describe the construction of *LoF*, and confront it with Niklas Luhmann's ontological and epistemological premises.

I show how ***LoF* must be considered a protologic, or research into the fundamentals of logical systems. The clue to its understanding is to be found in its profoundly topological conception of common mathematics and (Boolean) algebra.**

Both are explained as direct offspring of their planar orientation. **Selfreference is a justified instance of an extended, more intricate topological arrangement. Its consequences for ontology (non-identity) and epistemology (autology)**, I argue, have been adopted correctly by Niklas Luhmann. Separate sections are devoted to **how Spencer-Brown's notion of re-entry relates to Luhmann's definition of system/environment**, and to a comparison between Luhmann's and Parsons' functionalism.

KEYWORDS: epistemology • Niklas Luhmann • **self-reference** • social systems • George Spencer-Brown

I. INTRODUCTION

The single most striking characteristic of George Spencer-Brown's *Laws of Form* (Spencer-Brown, 1994 [1969] [hereafter *LoF*]) is the variety of misunderstandings concerning its reception.

Its basic idea is actually quite easy: **'form' or 'something' is identical to the difference it makes (with anything else), and (thus) eventually different from itself.**

All 'something', or 'form', or 'being', is explained as **the residual of a more fundamental level of operations (namely the construction of difference)**, including the 'calculus of indications' explaining the very *Laws of Form*. Due to its constructivist nature, the calculus has enjoyed admiration from a variety of people, some of whom are regarded as being of major importance in their respective scientific disciplines. After a meeting with Spencer-Brown in 1965, the philosopher and logician **Bertrand Russell** congratulated the young and unknown mathematician for the power and simplicity of this calculus with its extraordinary notation. In 1969, shortly after the publication of *LoF*'s first edition, the father of cybernetics **Heinz von Foerster** enthusiastically described it as a book that 'should be in the hands of all young people' (von Foerster, 1969). In the cybernetic tradition, by the way, *LoF*'s resonance is undiminished. The international journal *Cybernetics and Human Knowing* published a Charles Sanders Peirce and George Spencer-Brown double issue in 2001; there exist two extensive websites with *LoF* material and new Spencer-Brown mathematical work (see 'Spencer-Brown related sources' at the end of this article); and a revised English edition of *LoF* is forthcoming. One would conclude that *LoF* is very much alive indeed. But, as said above, appraisal for the calculus is certainly not univocal. There exist (some very advanced) criticisms of the calculus. Some authors regard it as misconstrued from its very beginning: the *Laws of Form* is no more than the *Flaws of Form* (Cull and Frank, 1979). The greater bulk of disapproving comments is, however, less than a spelled out, intricate argument. In general, it aims at the status of *LoF* within the mathematical tradition, and rejects it as a mere

variant of Boolean algebra, simply using a new notation. *Nil novum sub sole*, so to say. Whatever be the case, *LoF*'s thinking, especially where it concerns its far-reaching constructivist implications, has clearly not yet been well established. Spencer-Brown's (promising) claims notwithstanding, the context of his work, its notation, and its exotic vocabulary need a great deal of clarification.

For that very reason, the adoption of the calculus in contemporary sociological theory cannot be an obvious course. And yet, some sociologists, most notably sociologists working in the systems theoretical tradition of **Niklas Luhmann**, work with it 'as if it were not only common knowledge, but as if one had fully grasped the transformation of the deep ontological structure it induces' (Clam, 2000a: 69). This is most certainly a reason for surprise or doubt.

What does it mean when concepts (as 'forms') are consistently formulated as a distinction? In an example, what is the sense in defining systems theory as the theory of the difference between system and environment?

Next, is Luhmann's use of paradox, another central notion in *LoF*, more than an inflated postmodernist rhetorical device? Why does Luhmann insist on **constructing a circular epistemology** (i.e. sociology as a way of society to picture itself in itself)?

And why, above all, does Luhmann claim his theory to be universalist yet not solipsist? It is deplorable that the aforementioned reasonable doubts have generated a stream of publications harshly rejecting all Luhmannian theory. Danilo Zolo, for instance, has denounced the theory as a very complicated version of circular reasoning (1986, 1987). Gerhard Wagner (1997), on the other hand, specifically attacks Luhmann's epistemological grounding in *LoF*. Those differentialist claims, so Wagner argues, are no more than the foundationalist or essentialist thinking to which Luhmann himself claims to react.

In the following, I intend to tackle exactly these problems. I do so by systematically discussing the construction and argumentation of *LoF*, (1) as I believe it holds the key to itself and to the sociological claims of Niklas Luhmann, but also (2) because such analysis has been conspicuously absent in existent literature.

A great deal of attention will be paid to **problems associated with the circular construction of the calculus**.

At all times one should be aware of the difficulties or impossibilities of presenting circularity in a circular way: at least the medium of the book or oral presentation demands that we proceed linearly, i.e. respectively from the first to the last page, or from the opening to the concluding remarks.

As we shall see, this limitation (or, if one wants, 'paradox') contains the solution to a rightful understanding of *LoF* and Luhmannian theory construction – **'reason, or the ratio of all we have already known, is not the same that it shall be when we know more'** (William Blake).

I will start by showing how *LoF* relates to the mathematical tradition, and how this refutes a great part of existing criticism (section II). Next, after a treatment of the calculus' topological notation, I briefly show **the linear development** of the calculus out of the **primary arithmetic and primary algebra** (section III).

The planar foundation of both in particular allows us to understand why the grounding of a theory of (social) systems in Spencer-Brown's calculus can hardly be an obvious course of theory building (section IV).

Yet, **the presentation of self-reference** in the calculus notation, as Spencer-Brown demonstrates, is possible if and only if we are prepared to change the medium in which we are writing. **Selfreference defies presentation in plane space, yet can be presented in topologically more intricate versions of space** (section V).

As we will see, the latter corrodes **our most profound ontological presuppositions** radically (section VI); on a higher level, it is also responsible for sharp differences between the systems theories of Talcott Parsons and Niklas Luhmann (section VII). Last but not least, *LoF*'s altered treatment of space (and its relationship with time) allows an exploration of the peculiar epistemologies of both Luhmann and Spencer-Brown (section VIII).

II. STARTING POINT: A NONNUMERICAL ARITHMETIC

Before the discussion can commence, I should draw the reader's attention to the extraordinary economy with which Spencer-Brown equipped the calculus. This is *not* a common logical calculus founded on postulates. It is not even a logical calculus. The *Laws of Form* must be studied as a book of mathematics, an 'arithmetic whose geometry as yet has no numerical measure' (Spencer-Brown, 1994 [1969]: xi). No numerical measure, indeed! What does that mean? As Spencer-Brown rightfully underscores, we find ourselves here in the primitive a priori dimension of all notation: two-dimensional space.¹

1. Spencer-Brown at the Esalen conference (<http://www.lawsofform.org/aum/session1.html>): Mathematics is, in fact, about space and relationships. A number comes into mathematics only as a measure of space and/or relationships. And the earliest mathematics is not about number. The most fundamental relationships in mathematics, the most fundamental laws of mathematics, are not numerical. Boolean mathematics is prior to numerical mathematics. Numerical mathematics can be constructed out of Boolean mathematics as a special discipline. Boolean mathematics is more important, using the word in its original sense: what is important is what is imported. The most important is, therefore, the inner, what is most inside. Because that is imported farther. Boolean mathematics is more important than numerical mathematics simply in the technical sense of the word 'important'. It is inner, prior to, numerical mathematics – it is deeper

What we will be doing here, to put it bluntly, is drawing figures in sand, or on a piece of paper. Interestingly, this is what constitutes the challenge for a 20th or 21st-century public:

the level of investigation is as deep as being 'beyond the point of simplicity where language ceases to act normally as a currency for communication' (Spencer-Brown, 1994 [1969]: xxviii).

Our investigations will have to take place at a prediscursive level (Clam, 2000a: 68–9), **at a level where 'something' comes into being so to speak. This is very different from the level of number, and certainly logic, which is not so much concerned with the world but with the rather limited domain of our (human) cognitive relationship with the world.**

'Logic is not, and has never been, a fundamental discipline', Spencer-Brown therefore argues (Spencer-Brown, 1994 [1969]: xi). And for the same reason, postulates cannot exist here.

Spencer-Brown departs from a very basic experience of dealing with the world, with 'things', 'stuff'. This in itself makes the calculus a true rarity in the history of mathematical thought. I concur with Varga von Kibéd and Matzka (1993: 58) that Wittgenstein's *Logisch-philosophische Abhandlung* (the *Tractatus*), and in several respects Charles Sanders Peirce's work, are the kind of inquiry closest to the one presented in *LoF*.²

2. A very good illustration of the latter is a series of articles published in a special double-issue of *Cybernetics and Human Knowing* (2001), subtitled *Peirce and Spencer-Brown: History and Synergies in Cybersemiotics*. It is particularly important when it comes to the direct relationship between Peirce's notation and the *Laws of Form* (Engstrom, 2001).

In view of its rigorous confinement to the very fundamentals of logical systems, *LoF* is most acutely referred to as a **protologic**: a research into ordinary arithmetic, rather than ordinary algebra, or 'an inquiry into the pre-discursive laws emerging with the most elementary position of "something". These laws must be situated at a level preceding the level of expression grasped by classical logic' (Clam, 2000a: 68–9: cf. Spencer-Brown, 1994 [1969]: 96; Kauffmann, 1987, 2001a, 2001b).

Thus, *LoF* anticipates and wards off the major part of its critics at its most elementary level. This is important: when Kuroki Gen, a harsh critic of *LoF* describes the latter as a reformulation of propositional logic or Boolean algebra, he is at least neglecting the calculus' construction, and possibly ignorant of the meaning of its very starting point. We will encounter the consequences of this misunderstanding later.

This being said, we can proceed to what Spencer-Brown grants us in order to commence calculating (Chapter 1 in *LoF*). And that is not much.

Spencer-Brown is very cautious not to break with the objective of starting from the very beginning. He simply delivers **a definition of form** ('Distinction is perfect continence', and two axioms contained in the definition⁴

4. As one sees upon closer examination, both the law of calling and the law of crossing refer to the 'closure' or 'continence' of the form. On the meaning of continence, and the importance of its epistemology, see Varga von Kibéd and Matzka (1993: 60; see *infra*). Beyond doubt, it contains hints to **the form of self-reference**, explained in chapters 11 and 12. 'A mark or sign intended as an indicator is self-referential,' writes Louis Kauffman (1987: 58) as well.

(1) The law of calling refers to **the descriptive aspect of distinctions**. Once (a delineated) something has been given a name (call), recalling it does not alter it – 'the value of a call made again is the value of the call'.

(2) The law of crossing concerns **the injunctive or more clearly operational aspect of distinctions**. Here, a difference 'does make a difference'.

One can only be in the form, or not – 'the value of a crossing made again is not the value of the crossing'. Yet, its mathematical economy notwithstanding, let us not be mistaken about the *LoF*'s intentions:

The theme of this book is that a universe comes into being when a space is severed or taken apart. The skin of a living organism cuts off an outside from an inside. So does the circumference of a circle in a plane. By tracing the way we represent such a severance, we can begin to reconstruct, with an accuracy and coverage that appears almost uncanny, the basic forms underlying linguistic, mathematical, physical and biological science, and can begin to see how the familiar laws of our own experience follow inexorably from the original act of severance. (Spencer-Brown, 1994 [1969]: xxix)

As will be clear, this passage contains *LoF*'s undeniably universalistic (and thus circular) aspirations: **starting out from an original act of distinguishing, *LoF* intends to describe its consequences for:**

(1) **the possibility of the world ('things' as form);**

(2) **the possibility of developing a (cognitive) relationship with the world of things (knowledge or 'cognitive categories' as form); and**

(3) **eventually, the possibility of describing the possibility of discovering these possibilities (the *Laws of Form* as the precondition of all form, or the universe as 'what would appear if it could' (Spencer-Brown, 1994 [1969]: viii).**

The latter concerns **the pure circularity of the calculus: the Form as an explanation of itself**. It is this part as well that led Heinz von Foerster to link *LoF* with Wittgenstein's 'problem of the world' (Tractatus §60; 3.333): i.e. **the fact that the world we know is constructed in order to see itself**, while that appears to be a logical impossibility.

Boe: *LoF* 105

III. FORMS TAKEN OUT OF THE FORM

But discussing that is too early for now. Let us commence calculating. As should be expected from this basic inquiry, the calculus – which is commenced in Chapter 2 subsequent to the outlining of the **conception of the primal form** (Spencer-Brown, 1994 [1969]: 1–2) – begins

with a command of surprising naïveté: ‘Draw a distinction!’ (Spencer-Brown, 1994 [1969]: 3). **‘Draw a line’, ‘make a distinction’, is the primal injunction.** As such, Luhmann would say, **one performs the operation of ‘observation’.** **One de-lineates something and simultaneously indicates one of the sides separated by the distinction.**

In order to express the conception of the ‘form’ through a formal notation, Spencer-Brown employs the \perp , the ‘mark of distinction’, a topological notation. At this stage of the calculus, **the mark \perp represents a ‘cross’ (descriptive) that also ought to be taken to mean ‘cross!’ (injunctive).**

The mark is, in Peirce’s sense, a **portmanteau-symbol**⁶ it combines both the aspects of plain denotation and an injunctive or instructive meaning to cross the distinction and indicate one of the separated sides: ‘Let any token be intended as an instruction to cross the boundary of the first distinction. Let the crossing be from the state indicated on the inside of the token. Let the crossing be to the state indicated by the token’ (Spencer-Brown, 1994 [1969]: 5).

This is no more than stating the obvious. **When we draw a distinction (e.g. a circle), then the distinction cannot be neglected; it has affected the space in which it is written, and we are, as such, ‘in’ the form. The first distinction literally is a first judgement, an *Urteil*, which determines everything coming after it. Once the distinction has been drawn, a ‘universe’ is there, and the gates to return to a state of nothingness are closed; that world is the mere ‘nameless origin of heaven and earth’⁷ the phenomenology of which is lost.**

The notation \perp (alternatively \lrcorner , or \llcorner) thereby expresses that topological *asymmetry* as well. **Simultaneously with the drawing of a distinction, one of the sides is indicated. The concave side of the mark thereby represents the ‘inside’ of the form, or the ‘marked state’.**

The other side is the outside; it is a nameless residual, an unmarked leftover, from which the marked side is delineated.

We must stress here that the drawing of the distinction and the indication of one of the separated sides are two simultaneous aspects of one operation. In Spencer-Brown’s terms: ‘We take as given the idea of distinction and the idea of indication, and that we cannot make an indication without drawing a distinction’ (Spencer-Brown, 1994 [1969]: 1). It is equally impossible to draw a distinction without making an indication. Why else would one draw the distinction at all?

The indication is the *motive* of the distinction (Spencer-Brown, 1994 [1969]: 1). For the time being, we can thus conclude that **form, indication, and distinction are implied within each other, not to say identical.**

For it is clear that **every observation implies the drawing of a distinction, and this implies in turn that every form has to be conceived of as a distinction:** ‘Call the form of the first distinction the form’ (Spencer-Brown, 1994 [1969]: 3).⁸ This then allows the reader to follow what could be called **a *syntax of form* (LoF, Chapter 2):** aspects of the form (‘name’, ‘content’, ‘value’ etc.), basic calculatory possibilities (‘the form of cancellation’/‘the form of condensation’), and more complex notions, e.g. the ‘unwritten cross’.

In a next step (Chapter 3 and further), the calculus is developed linearly (!) out of the aforementioned syntactical complex – the latter represent the rules of the game, so to speak. It grows into a *primary arithmetic* which serves, in turn, as the foundation for a *primary algebra* (Chapters 4 through the line of the argument does not demand we enter theorems’ consequences, or canons developed here)⁹

At several points in the appendices, but also in the preface(s), introduction and the 'note on the mathematical approach', the difference between these is stressed, and Spencer-Brown definitely favours the primary arithmetic over the more commonly investigated level of algebras (e.g. Boolean algebra) (1994 [1969]: xxi–xxiii; 87ff.).

Arithmetic, he says, is about the constants, the individuality of form, and the individuality of the calculatory relationships the form builds. The algebraist, on the other hand, 'is not interested in the individuality of numbers, he is interested in the generality of numbers. He is more interested in the sociology of numbers' (Spencer-Brown, 1973). The formulation of the arithmetic was thus formative to the development of an algebra (Boolean) in the first place:

So, to find the arithmetic of the algebra of logic, as it is called, is to find the constant of which the algebra is an exposition of the variables – no more, no less. Not just to find the constants, because that would be, in terms of arithmetic of numbers, only to find the number. But to find out how they combine, and how they relate – and that is the arithmetic. (Spencer-Brown, 1973)

Elena Esposito has speculated that **both the primary arithmetic and the primary algebra may be instrumental to a sound understanding of cybernetic *constructivism*, especially where it relates to the difference between first order and second order observations** (1993: 99–100).

It all boils down to appreciating the arithmetic and the algebra as autonomous parts of the calculus that correspond to existent (because observable) systemic levels, respectively the **level of elements and the level of systemic organization**.

The **arithmetic**, as Esposito argues, **represents the 'formalization of autopoiesis'**. Here, **everything is about the execution of rules relating to constants ('specific objects')**. It is **a first order level of observation, a level where there can only be awareness of the *existence of form***.

The **algebra**, which could be constructed through the 'theorems of connexion', is a different matter. **This truly is a *calculus taken out of the calculus*, a level where the forms developed in the arithmetic are the object of other forms at a higher level (in turn bound by the rules of the arithmetic!). It is about arrangements (and hence: indication and distinguishing) of arithmetic forms (distinctions). In a sense, it is the systemic level.**

Esposito explains: The algebra formalizes **a specific type of autopoiesis** (and thus requires the validity of all arithmetic formulae): **the autopoiesis of a system, the operations of which are observations**. Yet, it remains a fact that its operations (including the operations of observation) can only be observed by an external observer. **This contains an openness which implies and eventually requires the integration of first order observations with observations of higher orders.**(Esposito, 1993: 104–5)

But however tempting Esposito's metaphorical use and/or explanation of the different levels may be (and I am certainly not saying Esposito's remarks are entirely wrong!), it is mathematically unsound: **autopoiesis is an issue neither in the primary arithmetic nor the primary algebra. What we are doing here is still drawing distinctions in the plane, discovering how they relate, how they may cancel each other out.**

IV. INTERVENTION 1: LOF AND SOCIAL SYSTEMS

The reader will understand that this leads to further doubts: **how is the notion of 'form' in the calculus of indications to be linked to a theory of social systems?**

By no means should the calculus of indications be understood as a 'brand' of systems theory. I repeat: the calculus is best viewed as a *protologic*; it was primarily written in reaction to some assumptions held in logic. And being a *proto*-logic, it was not even stamped as a logical calculus, but as a *mathematical inquiry*.

Another difference, however, between the Spencer-Brownian calculus and Luhmann's systems theory is that the former mainly represents finite forms (as the calculus demands, they exist as a finite number of crosses), whereas **social systems by definition hold out the prospect of infinity. They have never been set in motion 'at a certain point in time'**, as such a point would presuppose an earlier communication to which they could connect; and, vice versa, they don't break off at a certain point, as such a point would hold out the prospect of continuation.

In Spencer-Brown's calculus, **potentially infinite forms** are mentioned only where the calculus has been taken 'so far as to forget it' (Spencer-Brown, 1994 [1969]: 68).¹⁰ An attempted coupling of the *Laws* and the theory of social systems should therefore come as a surprise.

Let us take a look at how an apparent contradiction contains the key to its solution. First of all, **how do we define a system?**

A system exists when there is something capable of identifying a specific operation as belonging to itself, i.e. when there is something capable of discriminating that operation from operations that do not belong to itself (with attention to the sheer tautology of systemic operations).

A system then uses the products of preceding systemic operations for the performance of new and different operations, again identified as belonging to the system, not to its environment.

Systems thus necessarily carry an image of what they are not, although in a truly ambiguous way. This operational mode is designated as **self-reference**.

Self-reference expresses the unity the system creates for itself. It indicates that a system refers to itself in all its operations: '*There are systems that can develop a relationship with themselves and can distinguish this relationship from relationships with the environment*' (Luhmann, 1995: 31).

This conceptualization of **self-reference** in the terms of the *LoF* does not seem a self-explanatory course. After all, it would come to mean that **forms, distinctions (e.g. system/environment) develop a relationship with themselves, although self-contact is implied as being an impossibility in the definition of the 'primal form'**.

Once more, I stress that **the operation(s) of distinguishing and indicating should be studied as a single operation**. And once more, I must emphasize that **the indication is the one and only motive of the distinction**.

Taken together, does this not mean that the distinction is employed simply in order to be forgotten in the indication?¹¹ Consequently, **if the whole range of the distinction is in itself the residual of an observation, how can self-reference possibly be realized? Is not self-reference an impossibility, as it implies the distinction's capability of referring, i.e. indicating, itself in itself**, and employing earlier indications for the production of new indications in the (same) form? Is self-reference not excluded in the very definition of the primal form? **In brief: is self-reference not inhibited because of the fact that distinctions, differences 'make a difference'?**

V. RE-ENTRY OF THE FORM INTO THE FORM

And yet: is this really true? **Do all distinctions make a difference?** In some obviously neglected but crucial passages of the 'appendix' to the calculus, Spencer-Brown reminds us of the use of **covert conventions** (Spencer-Brown, 1994 [1969]: 85) in mathematics: we have agreed to some rules without being consciously aware of the fact we did so.

In the beginning of the calculus and, for that sake, in this chapter, the reader has for instance assumed that the distinctions were drawn in a *plane*: a piece of paper, for instance, or the surface of the earth. As we know, **distinctions drawn in a plane do indeed build a distinction.**

But the use of a different mathematical medium makes things a lot more complicated, to the point that seemingly obvious facts are, in fact, not self-evident at all. **If, at the outset, we had confined ourselves to writing on a torus (a 'doughnut'), for instance, the distinction would not have constituted a distinction.**¹²

12. Spencer-Brown (1994 [1969]: 86):

The fact that men have for centuries used a plane surface for writing means that, at this point in the text, both author and reader are ready to be conned into **the assumption of a plane writing surface** without question. But, **like any other assumption, it is not unquestionable**, and the fact that we can question it here means that we can question it elsewhere. In fact we have **found a common but hitherto unspoken assumption underlying what is written in mathematics, notably a plane surface.** Moreover, it is now evident that if a different surface is used, **what is written on it, although identical in marking, may be not identical in meaning.**

Clearly, **our unconscious choice to write in a plane, on a piece of paper— that has made the real difference. If we are only willing to work with a different medium, with a different conception of the spaces in which the distinctions are drawn, it may very well produce a wholly different arithmetic, algebra, and logic. Such willingness would, moreover, not be without a cause.**

As we explained above, **we do in fact assume the existence of forms (i.e. systems) that are thoroughly self-referential, that thus demand a different topological treatment (as they defy representation in the limiting terms of a plane surface, or even Euclidean space).**

During his career as a civil engineer for British Railways (Spencer-Brown, 1994 [1969]: 99), George Spencer-Brown and his mysterious brother D.J. Spencer-Brown had already developed special-purpose computer circuits that exhibited all characteristics of self-referential expressions, the prohibition of their use in conventional logic and mathematics notwithstanding.¹³

For Spencer-Brown, the question is thus a purely mathematical one. His interests lie with showing **the validity of imaginary values** (e.g. $\sqrt{-1}$), the *use* of which has been common in, for example, electromagnetic theory. As they can be used meaningfully for the solution of equations which cannot be solved otherwise, we must accept 'imaginary' as a 'third' category independent from (1) true (tautology: $x = x$) and (2) untrue (contradiction: $x = -x$).

For Niklas Luhmann, the problem is to **describe self-referentially operating social systems**, consisting of operations which take their own results as a base for further operations. **These are forms that 'in-form' themselves.**

In the mathematics of *LoF* (Chapter 11), the following solution for our problem is proposed: **let us conceive of 'space' in a different, operational, way, i.e. space as a relation between elements** (Junge, 1993: 127).¹⁴

If we are able to **abandon the idea of space as a Euclidean 'container'** (i.e. space as something 'in which' things are positioned), it is indeed possible to **conceive of self-reference as forms turning up¹⁵ in their own form.**

Returning to the calculus, Spencer-Brown insists that **we must therefore allow some way of contact between the separated sides of the distinction written in the plane surface.**

In order to show the self-reference of a form/distinction, the distinction must, quite literally, be undermined. Let us therefore dig holes, **tunnels**, under the surface in which the distinction appears, and ‘corrupt’ (Latin, *corrumpere*, to break together)¹⁶ the cross (Spencer-Brown, 1994 [1969]: 59ff.; 100ff.).

That space is a torus. If considered operationally, distinctions written on a torus can subvert (turn under) their boundaries, travel through the torus, and re-enter the space they distinguish, turning up in their own forms, thus capable of developing some kind of contact with themselves.¹⁷

17. This topological solution seems to refer to a famous dictum: ‘the medium is the message’ (Marshall McLuhan). And indeed, there exist some attempts to interpret *LoF* in a medium theoretical way (Lehmann, 2002).

Clearly, **such self-referential form cannot be decided (Latin, *de-cedere*, ‘to cut off’) in the plane. The marked state cannot be clearly distinguished from the unmarked state anymore, leading to ‘indeterminacy’. The form is neither marked nor unmarked. It is an imaginary value, flipping between marked and unmarked, thanks to the employment of time.**¹⁸

However, this does not preclude its existence: **The value [of self-referential forms] being indeterminate in space, may be called imaginary in relation with the form. Nevertheless it is real in relation with time and can, in relation with itself, become determinate in space, and thus real in the form.** (Spencer-Brown, 1994 [1969]: 61)

Self-referentially operating systems should thus be understood as the operational difference between themselves and their environment, a difference that is made through some sort of self-referential oscillating between the two sides of the distinction (i.e. system and environment).

By means of self-reference, the environment ‘out there’ can be observed as being drawn topologically into the ‘inside’ of the system (compare the inside and outside of a Möbius ring).

This is the meaning of **re-entry**: the two sides of the distinction are re-inserted into one of its parts. Spencer-Brown repeats the notational ramifications of such subversion: **In a simple subverted expression of this kind, neither of the parts are, strictly speaking, crosses, since they represent, in a sense, the same boundary.**

It is convenient, nevertheless, to refer to them separately, and for this purpose we call each separate part of any expression a marker. Thus a cross is a marker, but a marker need not be a cross. (Spencer-Brown, 1994 [1969]: 65) The distinction could thus also be said to have been alienated from its original intent or motive (i.e. indicating one separated side), and this by value of being processed within the form (system), in order to safeguard the difference between itself and other distinctions *over time*.

The aforementioned notational arrangement does, however, have intriguing consequences for **the form’s being**. The excursion through the tunnel of the torus, and the consequent time employed to return into itself, make the self-referential form peculiarly look as if it is shifting between what it is indicating (‘cross!’) and what it uses to make indications (‘marker’). The self-referential form is **flippety**: **‘I am the link between myself and observing myself’** (von Foerster, 1990: 14). In the parlance of ontology (see *infra*): **the self-referential form is both identical to and different from itself** (Schiltz and Verschraegen, 2002:esp. 65ff).¹⁹

VI. LoF AS ONTOLOGY

With the mathematical visualization of self-reference in mind, it may be instructive to reconsider an important critique on Luhmann's notion of 'system'. Interestingly, some authors – most prominently represented by Gerhard Wagner (1997) – seemingly assume that Luhmann has proposed to simply replace a thing's or system's identity by means of a difference, namely the difference between system and environment, just like that.

Obviously, such a shift has not been the case. Rather, what is lacking in the critique is due [attention to the growth of the calculus' injunctions in the direction of the 'form' of self-reference.](#)

Whereas Luhmann himself has, on several occasions, referred to systems theory as an invitation to draw a distinction between system and environment, that distinction is an obvious advance on the topological ramifications prominent only in the concluding chapters of the calculus. Clearly, Wagner mistakenly views the difference between system and environment as the *immediate* offspring of the primal construction 'draw a distinction!'; his argument has not 'followed' up to the coda, let alone selfreference having been 'understood'. He is still in the plane.

Consequently, he is **myopic concerning the operational aspect of self-reference**. Hence, the difference between system and environment cannot be evaluated in its full complexity. As a matter of fact, it must ultimately come to be seen as a rather trivial reiteration of foundationalism: 'The fact is that, by the way in which Luhmann understands foundational difference, he practically commits his position to identity' (Wagner, 1997: 391).

In such a **mistaken view system and environment can easily and erroneously come to be conceived of in terms of a polar opposition** (1997: 397), quite similar to Hegel's **notion of negativity** (1997: 399 ff.).

As my remarks have hopefully made clear, the elaborate notion of a system as a self-referential form can only be realized in the more advanced chapters of the *Laws*, namely Chapters 11 and 12, in which there is made mention of the **re-entry**.

The system's self-reference can thus only be defined as the act of selfreference, as self-referential performance. And this, as we have seen, demands a quite intricate topological arrangement. **The system must reflect, in the formal sense, itself and its environment as a corollary of itself in all of its operations.**

It can secure the connectivity of its operations only by establishing itself as an imaginary value, and by employing the time of the tunnel to develop a relation with itself. In short, **imaginary space is the only topological possibility for a system to be systemic.** For that reason, **the difference between the system and the environment cannot be an essentialist difference**, let alone a new version of foundationalist thought:

It does not cut all of reality into two parts: here system, there environment. Its either/or is not an absolute; it pertains only in relation to the system, though objectively.

It is correlative to the operation of observation, which introduces this distinction (as well as others) into reality. (Luhmann, 1995: 178) This **operational aspect** apparently provides the clue to the numerous misunderstandings about Luhmann's ontological premises. And time after time, the peculiar position of the environment has been at the core of the problem. Yet, if you are aware of the topological qualities of the torus, you can easily understand that position. **The environment is not so much out there as in there: it simply emerges out of the re-entry of the distinction into itself.**

The environment is constructed by the system; it exists only with the form of the system, i.e. if there is a boundary that can be employed in order to re-enter the system's own inner space²⁰.

20. This is not to say that there is a complete and perfect equivalence between the system and the environment; rather, there is a **fundamental asymmetry, to the advantage of the system**. This basic asymmetry means that **the environment does not contain distinctions; it is not a piece of information**. Distinctions are found only in a system. **Systems observe, while there is nothing self-referential or systemic to the environment**.

This form-centred conceptualization has clearly parted with more established distinctions such as **subject versus object, man versus world, or self versus difference**. **In LoF and systems theory, everything, all emergent reality is discussed as the corollary of a construed difference.**

So what are the ramifications of self-reference for **our 'ontology of the world'** (Kauffman, 2001b: 137)? Central to our discussion here is the **connection between operationalism and form**.

Systemic operations, we have stressed, presuppose self-contact and, vice versa, self-contact implies systemic 'in-formation'. Clearly, the form is on its own, it is a self-sufficient and self-engendering reality.

Actually, the definition of the primal form, stated at the very outset of the calculus of indications, had already made this clear: 'Distinction is perfect continence' (Spencer-Brown, 1994 [1969]: 1)²¹

21. As Matthias Varga von Kibéd and Rudolph Matzka (1993) stress, continence should be interpreted on the basis of its etymological relationship to the Latin 'continere', **'to hold together'**. Thus, 'distinction is perfect continence' makes clear not only that the origin of the two sides is to be contained in the distinction, but also (and primarily) that **the form has no anchoring in any outside reality or foundation** – it is the context of itself, it is 'closure'.

But at this stage of the calculus, what we have already known is not the same as what we know now (see the citation of William Blake in the introduction). **At this point we realize that 'form' is the symbol of the world or the universe; all form is part and product of a self-engendering self-referential whole²² of which even the first form must be embedded in a further form** (most fundamentally the difference between drawing a distinction and deciding not to do so)²³

22. It is important to stress similarities between *LoF* and **lambda-calculus**. A lambda domain is a class of objects that can act on one another to form new objects of the same kind. It thus **presupposes self-reference or recursivity**. Church and Curry (1933) recognized the latter most clearly, and in this respect proved the 'fixed point theorem', saying: 'For every element F in the lambda domain, there is a J in that domain for which $F(J) = J$ '. Louis Kauffman (2001a: 102ff) provides most obvious clues on the recursivity of the universe and mathematics in a **comparison of Spencer-Brown's ideas with ideas of Charles Sanders Peirce**.

23. I surmise this is the meaning and function of the mysterious 'unwritten cross', already introduced in the very beginning of the calculus: 'Suppose any sn[primal space] to be surrounded by an unwritten cross' (Spencer-Brown, 1994 [1969]: 7).

This **formal introversion** (Latin *intro-vertere*, turning inside), this very self-reference, refutes essentialism. After all, **while we may take it that the universe undoubtedly is itself, i.e. indistinct from itself**, we must accept the fact that, **as self-reference, it is indeed false, or distinct, to itself**: We may take it that the world undoubtedly is itself (i.e. is indistinct from itself), but, in **any attempt to see itself as an object, it must, equally undoubtedly act so as to make itself distinct from, and therefore false to, itself. In this condition it will always partially elude itself**. (Spencer-Brown, 1994 [1969]: 105)

The world is not 'what there is' (Quine, 1953). Yet, this foundationalist crisis à la Kurt Gödel's theorem of incompleteness should not be seen as a reason for despair. **Self-referential paradox, meaning indeterminacy, must be construed as the price systems and the world pay for the possibility of operations, activity, and systemic evolution.**

For contemporary systems theory, **paradox is not seen as an accident to be avoided, but rather as the creative presupposition of the whole construction.** Paradox is not the fatal end, the definitive failure of all ontological constitution. On the contrary, **it is the starting point of a history, a movement of systemconstitution, full of risks and bifurcations. Paradoxes do not make things impossible, but rather possible.** (Clam, 2000b: 133)

The French philosopher Jean Clam has therefore speculated that it may be analytically fruitful to employ a difference between **apophantic** and **ergetic paradoxes**, respectively **paradoxes occurring in logical expressions** (in the plane!) and **paradoxes imminent in operations, or systemic space.**

In the apophantic sense, paradoxes do indeed block observation: they do defy determinacy, and may therefore be judged destructive or corrupt according to the foundationalist tradition.

But the excursion through the tunnel has shown that there is a merit in subversion: **what apparently blocked cognition has become an operational loophole, a compelling chance for system genesis.**

Systems must operate, in order to achieve the fictitious unity that could not be achieved by the ontologically more elegant way of self-identity and integrity. Systems must operate, in order to bypass situations of a structural standstill. And semantically, systems must operate in order to cover up the devastating consequences of manifest inconsistency and contingency: **deparadoxicalization.** Operating is always the introduction of a component that avoids the standstill, because **it broadens the space of possibilities.** The operating of systems is nothing else than this handling of components which create more possibilities and condensing them into a self-contained but not-finalizable ergetic whole. (Clam, 2000b: 135)

VII. INTERVENTION 2: LUHMANN VERSUS PARSONS

In retrospect, one will agree that the ever growing prominence of paradox in Luhmann's thinking has changed the concept of social system in ways so fundamental that a sociologist such as Talcott Parsons could not have imagined.

At no point, we must concur, can a system be described in terms of invariant structural characteristics.

Confronted with the utter impossibility of unity and consistency, in favour of indeterminacy and contingency, **systems emerge as mere sequences of ongoing operations.** They are no more than a momentary derivative of passing operations, characterized by a self-reinforcing restlessness.

Admittedly, Luhmann has never been a committed structuralist. In *Social Systems*, he rejected structuralism on the grounds that 'structuralists have never been able to show how a structure can produce an event' (1986: 174; see as well Luhmann, 1995: 377ff). His theory of social systems has therefore **subordinated structure to function**, and has **shifted the focus from structure to event**, the network of which produces the unity of the system, in the event only. But through time, the **concept of autopoiesis**, which expresses the self-production of the network, has undergone some major changes as well. Whereas the notion had originally been defined in close reference to the way it was designed by Humberto Maturana, Luhmann forsook this definition almost completely in the 1990s. Finally, the notion would be fully rewritten in the terminology of the calculus of indications: '

Autopoiesis is thus not to be conceived as the production of a peculiar "Gestalt". Crucial is rather the formation of a difference between system and environment' (Luhmann, 1997: 66).

Autopoiesis, the reader will understand, is nothing but the form of a system's basal unrest, the abbreviated expression of the system's concern with getting around its non-identity. The strong self-referential, and hence reflexive, bias of the notion shows what that means. **Enclosing itself in itself, i.e. enclosed in itself, the form incessantly crosses its own internal boundary, thereby adding to its level of complexity, but never able to become identical to itself** (see Clam, 2000b: 136).

This latter point may be helpful in understanding Luhmann's particular brand of functionalist methodology. Back in 1970 he had already criticized Parsonian functionalism on the grounds of assuming a semi-identity of *function* and *causality* (Luhmann, 1991 [1970]). Clearly, the **notion of causality**, implying necessity and absoluteness, is at odds with a theory that converges around **contingency** – in politics, in law, in science, in intimacy, in art: in brief, modernity (Luhmann, 1998: 44–62)!

Luhmann therefore returns to Kingsley Davis's critique of the functional method (1959) and manages to turn this critique inside out: the rejection of functionalism is – in a typically functionalist guise – employed as a solution for some conceptual deficiencies of the functionalist method.

Basically, **the relationship between function and causality is asymmetrized**: causality must be classified as one exceptional instance of function. And second, functionalism is outlined as a method for *comparing* the potential of systemic arrangements aimed at the maintenance of the system's unity, rather than for indicating the 'systematic' relationships between function and achievement.

Luhmannian functionalism is a functionalism of difference, and as such is more than a mere rhetorical upgrading or fine-tuning of a well known functionalist repertoire. After all, the quest for historically contingent and factually variable functional equivalencies effectively avoids the structural determination of theoretical judgement (Luhmann, 1995: 52).

With respect to content, attention shifts from the functional arrangement to what could be called **the construction of problems**. And again we encounter self-reference here. Rejecting a social system's (structural) permanence, and subscribing to the idea of **systems as forms that react to their self-generated complexity, functionalist method also entails paying adequate attention to the way in which systemic problem solutions (functional arrangements) 'trans-form', expand the system's operational status, and thus re-enter the system's space at a new level**. At that level, the problem to which the functional arrangement initially reacted may have disappeared or may be encountered in a different, possibly more accrued, manner. Such are the methodological consequences of **self-conditioning self-reference**.

VIII. LAWS OF FORM AS AN AUTOLOGICAL CONSTRUCT

Finally, I promised a clarification of the metaposition of the notion of form far beyond the scope of its heuristical application. After all, after indicating the possibility of self-referential forms ('re-entry', Chapter 11), *LoF* offers a perspective on the position of the calculus ('Re-entry', Chapter 12).

The calculus, as a part of the universe, must be one possible form, distinguishing the forms it has been describing as forms making a difference. The very calculus of indications has been a 'tunnel' through which Spencer-Brown and the reader have traveled to arrive at **the form of the first distinction**, which is now seen as legitimized, justified by all canons, theorems, demonstrations and proofs that followed it. **The 'first distinction', was deliberate and historically contingent**. Yet, all that followed was its *necessary* consequence: **The whole account of our deliberations is an account of how [the first distinction] may appear, in the light of the various states of mind which we put upon ourselves** (Spencer-Brown, 1994 [1969]: 68; square brackets in original).

For that very reason, the clarification of the laws governing this universe must be considered a trivial matter: Coming across it thus again, in the light of what we had to do to render it acceptable, we see that our journey was, in its preconception, unnecessary, although its formal course, once we had set upon it, was inevitable. (Spencer- Brown, 1994 [1969]: 106)

The paradoxical combination of contingency (of the first distinction) and necessity (of its consequences) demonstrates in what fundamental respect the epistemology of the *Laws of Form* differs from classical epistemologies. **The calculus of indications, ultimately a function of itself, has established itself as an imaginary value.** It can be continued endlessly, as Spencer-Brown does not fail to indicate (Spencer-Brown, 1994 [1969]: 68).

On the one hand, its inclination towards the imaginary makes the calculus correlate with what it seeks to describe: **like reality or 'world', the calculus is 'form' that seeks to get hold of itself but does not manage to do so.**

On the other hand, its constructivism obviously implies the loss of a privileged position of (scientific) knowledge. At this point it is clear how *LoF* relates to Wittgenstein's problem of the world (cf. supra). Self-reference has come 360°.

It is not merely at the root of any possible universe. It also dominates and determines observations of the universe, and eventually observations of the *Laws of Form* governing both. This should affect scientific observations and scientific method considerably. It implies **a shift from a world of things to a world of observations.**

This is not just a world of the real: **'There is a tendency, especially today, to regard existence as the source of reality, and thus a central concept. But as soon as it is formally examined, existence is seen to be highly peripheral, and as such, especially corrupt (in the formal sense) and vulnerable'** (Spencer-Brown, 1994 [1969]: 101).

It is rather **a world of the possible**, and an observer's intention to draw distinctions.

Our understanding of the world thus cannot reside in some form of discovery of its present appearance (out there, beyond observation), but comes from remembering the conventions agreed to in order to bring it about. The task of the mathematician, whose interest lies with notational elegance and density, may hence lie with bringing the world back to its conventions, and abandoning all surplus arrangements. As is well known, Spencer-Brown's conclusions eventually border on the mystical: **'to experience the world clearly, we must abandon existence to truth, truth to indication, indication to form, and form to void'** (Spencer-Brown, 1994 [1969]: 101).²⁵

For Niklas Luhmann, however, when presenting a theory of social systems, the challenge is different. His task lies not with abandoning but rather with expanding. Clearly indebted to *LoF*, **Luhmann adopted the notion of form and the corollary notion of medium.** He has typically used a theory of the latter to identify **different types of medium in the social sphere**, speculate about their respective topologies, their transformative capabilities, their role in societal evolution, and so on.

It is revealing that **form/medium** came to permeate the whole of Luhmann's theory of society, eventually stretching beyond the original main distinction of system and environment, bringing about obvious **problems of theory construction** (Brauns, 2002).

Epistemologically, furthermore, Spencer-Brown's mathematical conclusions on re-entry are expressed as **the autology of the distinction between form and medium: form/medium is a distinction**, thus form²⁶.

26. This leads to the question of why Spencer-Brown does not employ a similar view as **form as the difference between itself and the medium in which it is written**. Peter Fuchs has argued that *LoF* does not need the notion of 'medium' as its field of inquiry is mathematics, and as such without heuristical aspirations.

As my above considerations on *LoF* show, I am not so sure this is the case. George Spencer-Brown makes mention of the notion of medium in at least two passages (see Schiltz, 2003). Furthermore, he obviously employs **the notion of medium in order to be able to show the possibility of self-referential forms (the medium of plane space versus the medium of the torus)**. Yet, I believe he does not pronounce it in view of his utmost attention for notational matters: Returning, briefly, to the idea of existential precursors, we see that if we accept their form as endogenous to the less primitive structure identified, in present-day science, with reality, we cannot escape the inference that **what is commonly regarded as real consists, in its very presence, merely of tokens or expressions**. (Spencer-Brown, 1994 [1969]: 104) In principle, *LoF* can suffice with its topological notation, as long as we are aware of its intricacies (e.g. the distinction between crosses and markers in Chapter 11).

It, (form UB) too, must reflect the triviality of its necessity. **As a self-referentially organized theory, Luhmann's systems theory represents its own boundary, and its limitations.**

The acclaimed universality of the theory can therefore never entail solipsism. If properly observed, the *Laws of Form* relate (relativize) the theory's universality to the notation employed, thereby outlining the distinction as its own limitation.

Conscious of its social formulation in the social sphere of society, the theory of social systems is simply one possible way of presenting society in society (*die Gesellschaft der Gesellschaft*). **It is only one possible form in the all-encompassing medium of meaning.**

This leads to an interesting question. **If the medium of meaning is indeed the ultimate medium of psychic and social systems, i.e. if meaning is 'the medium of itself', then what is its 'form', the distinction through which it can be expressed?** I perceive only one answer: *the medium of meaning must be identical to the difference between form and medium, and the re-entry of that distinction into itself.*

Its consequent indecidability is the symbol of our dealing with the world. It expresses the fact that all our attempts to get hold of the world are doomed to frustration (see Spencer-Brown, 1994 [1969]: 102 ff.).

Meaning as our phenomenology of this world can only be partial, as the difference between form/medium can only be actualized as a form. In mathematical terms: meaning is a lambda domain occupied by communications that, by acting on themselves (=being a function of themselves), produce new communications in the same domain which can in turn act on themselves and further expand the domain.

It will be clear to the reader that such far-going occupation with self-reference must change our view of Spencer-Brown's 'form', and Niklas Luhmann's system/environment and form/medium.

Their function lies most certainly not with the description of the 'objects' in their respective domains and their respective 'qualities' as qualities that are eternally true (i.e. observer-independent).

Rather, the self-referential construction of the universe and especially **the medium of meaning demands the construction of theoretical notions capable of reflecting themselves as an object (=communication) in their domains, expanding the domain's horizon beyond their own capability of observing that expansion.**

Seen in the terminology of topology, **form and form/medium are self-locators or fixed points**: they are the sole 'points' on the map of mathematics and social theory that coincide with the corresponding point in the terrain their disciplines are trying to map.

Such points contain their own explanation (i.e. their allo-reference and self-reference coincide). They are the pinnacle of self-reference in domains that are selfreferentially built. Therefore, both *LoF* and the theory of social systems are not only in the metaphorical sense a formulation of Quine's paradox. When applied to themselves, they 'yield a falsehood' (absolute because contingent).

Yet, therefore, just as Quine's paradox, they can be absolute theories, theories which are also **theories of themselves**. Ironically, the latter also constitutes their absolute weakness, I feel. When Niklas Luhmann, for instance, describes the epistemological premises of his gigantic theory of society as an invitation to rethink existing social theory, and to formulate theories that have themselves compared to his project, this must be seen as a (rhetorical?) illustration of his epistemological self-confidence, no more and no less. After all, it is in the nature of meta-theories not to tolerate epistemologies of a different brand. It is exactly their meta-nature that blocks the possibility of going beyond them – **self-reference is infinity in finite guise**, as Louis Kauffman also knows (2001a: 105).

It should be clear that different theories and different epistemologies will have to put to themselves the requirement of contingency and autology in order to qualify as a candidate for comparison after all. Whether this paradox has detrimental consequences is a question that must be left open here. It is only to hope that, as William Blake has said, 'reason, or the ratio of all we have already known, is not the same that it shall be when we know more

Michael Schiltz is Postdoctoral Research Fellow of the Fund for Scientific Research Section of Japanese Studies, Catholic University, Leuven. [email: Michael.Schiltz@arts.kuleuven.be]

Acknowledgement I would like to thank the anonymous reviewers at *Thesis Eleven*. I also thank Stefano Magnolo and Raffaele de Giorgi for their warm and professional welcome at the Center for the Study of Risk of the University of Lecce, Italy. Professor Nishibe Makoto deserves mention for kindly hosting me at the Faculty of Economics of the University of Hokkaido, Japan. I strongly hope to be able to cooperate with him in the future. Last but not least, I thank the Japan Society for the Promotion of Science for generously supporting my stay in Japan (September–December 2004) during which this article could be discussed.

Notes

1. Spencer-Brown at the Esalen conference (<http://www.lawsofform.org/aum/session1.html>):

Mathematics is, in fact, about space and relationships. A number comes into mathematics only as a measure of space and/or relationships. And the earliest mathematics is not about number. The most fundamental relationships in mathematics, the most fundamental laws of mathematics, are not numerical. Boolean mathematics is prior to numerical mathematics. Numerical mathematics can be constructed out of Boolean mathematics as a special discipline. Boolean mathematics is more important, using the word in its original sense: what is important is what is imported. The most important is, therefore, the inner, what is most inside. Because that is imported farther. Boolean mathematics is more important than numerical mathematics simply in the technical sense of the word 'important'. It is inner, prior to, numerical mathematics – it is deeper.

2. A very good illustration of the latter is a series of articles published in a special double-issue of *Cybernetics and Human Knowing* (2001), subtitled *Peirce and Spencer-Brown: History and Synergies in Cybersemiotics*. It is particularly important when it comes to the direct relationship between Peirce's notation and the *Laws of Form* (Engstrom, 2001).
3. Kuroki constructed an extensive website arguing against Spencer-Brown (in Japanese): <http://www.math.tohoku.ac.jp/%7Ekuroki/SB/index.html#abstract>
4. As one sees upon closer examination, both the law of calling and the law of crossing refer to the 'closure' or 'continenence' of the form. On the meaning of continenence, and the importance of its epistemology, see Varga von Kibéd and Matzka (1993: 60; see infra). Beyond doubt, it contains hints to the form of self-reference, explained in chapters 11 and 12. 'A mark or sign intended as an indicator is self-referential,' writes Louis Kauffman (1987: 58) as well.
5. In the *Tractatus*' original:
Eine Funktion kann darum nicht ihr eigenes Argument sein, weil das Funktionszeichen bereits das Urbild seines Arguments enthält und es sich nicht selbst enthalten kann. Nehmen wir nämlich an, die Funktion $F(fx)$ könnte ihr eigenes Argument sein, dann gäbe es also einen Satz: $\langle F(F(fx)) \rangle$ und in diesem müssen die äußere Funktion F und die innere Funktion F verschiedene Bedeutungen haben, denn die innere hat die Form $\phi(fx)$, die äußere die Form $\Psi(\phi(fx))$. Gemeinsam ist den beiden Funktionen nur der Buchstabe $\langle F \rangle$, der aber allein nichts bezeichnet. Dies wird sofort klar, wenn wir statt $\langle F(F(u)) \rangle$ schreiben $\langle (\exists \Pi): F(\phi u). \phi u = Fu \rangle$ (Wittgenstein, 1989 [1922]: 34).
6. References to Peirce's mathematics are not accidental here: even in notation, the resemblance of Spencer-Brown's form with Peirce's notation (e.g. the 'sign of illation') is striking. Excellent references here are Engstrom (2001) and Kauffmann (2001a).
7. Spencer-Brown uses this obscure passage from the first chapter of the *Tao-teking* as the opening quote for *LoF*.
8. Obviously, one must not necessarily agree with this conception; but, if so, one places oneself outside the calculus (and we are clearly not willing to do so here). In the calculus, one is expected to obey the injunctions of mathematical communication, and to obey only them, and them only: 'In general, what is not allowed is forbidden' (Spencer-Brown, 1994 [1969]: 3).
9. On how *LoF* may aid our understanding of Boolean algebra, see Meguire (2003).
10. Therefore, the reference to infinite forms emerges as equivalent to the famous phrase of §7 in the *Tractatus*: 'What we cannot speak about we must pass over in silence' (Wittgenstein, 1971 [1921]: 151). It is the part 'in' the calculus that embodies reference to the 'outside' of the calculus. Consequently, it has an equivalent problematic status: it is the paradox *saying* that there are *things* about which *nothing* can be *said*. Consider, in this regard, Bertrand Russell's remarks on §7 of the *Tractatus*:
What causes hesitation is the fact that, after all, Mr. Wittgenstein manages to say a good deal about what cannot be said, thus suggesting to the skeptical reader that possibly there may be some loophole through the hierarchy of languages, or by some other exit. (preface to Wittgenstein, 1971 [1921]: xxi)
11. With attention to the linguistic difficulties of describing the unity and difference of distinction and indication, see Schiltz and Verschraegen (2002: 65–70).
12. Spencer-Brown (1994 [1969]: 86):
The fact that men have for centuries used a plane surface for writing means that, at this point in the text, both author and reader are ready to be conned into the assumption of a plane writing surface without question. But, like any other assumption, it is not unquestionable, and the fact that

we can question it here means that we can question it elsewhere. In fact we have found a common but hitherto unspoken assumption underlying what is written in mathematics, notably a plane surface. Moreover, it is now evident that if a different surface is used, what is written on it, although identical in marking, may be not identical in meaning.

13. For examples of Spencer-Brown's engineering work, see: <http://www.lawsofform.org/patents/index.html>

14. This is not a particularly 'exotic' venture: Die Bestimmung von Räumen aufgrund der Relationen zwischen bestimmten Elementen ist nichts ungewöhnliches: Man konstruiert zum Beispiel eine Landkarte auf Grundlage der Entfernungen zwischen den einzelnen Orten. Diese Entfernungen lassen sich aber auf verschiedene Weisen messen: die Entfernung auf der Luftlinie in Kilometern ergibt andere Distanzen als die Kilometerzahl, die man mit dem Auto zu absolvieren hätte. . . . *Wenn man den Raum operational definiert, wird die am ihm geschulte Logik unter Umständen flexibler.* (Junge, 1993: 127–8; emphasis added)

15. Later in the discussion, the reader will understand why 'turning up' is the accurate term here.

16. 'To corrupt', synonymous to 'to destroy the integrity of' (Latin: *in-tangere*, 'untouched', undivided).

17. This topological solution seems to refer to a famous dictum: 'the medium is the message' (Marshall McLuhan). And indeed, there exist some attempts to interpret *LoF* in a medium theoretical way (Lehmann, 2002).

18. The reader must realize that time has thus been *created* as a consequence of a type of space, namely space in which form can relate to itself, and, as such, change (change being the measure of time). Time is thus nothing pre-given. Neither is space:

The first state, or space, is measured by a distinction between states. There is no state for a distinction to be made in. If a distinction could be made, then it would create a space. That is why it appears in a distinct world that there is space. Space is only an appearance. It is what would be if there could be a distinction. (Spencer-Brown, 1973)

19. Kay Junge (1993) explains this as the medium (of the torus) 'blocking' direct self-reference.

20. This is not to say that there is a complete and perfect equivalence between the system and the environment; rather, there is a fundamental asymmetry, to the advantage of the system. This basic asymmetry means that the environment does not contain distinctions; it is not a piece of information. Distinctions are found only in a system. Systems observe, while there is nothing self-referential or systemic to the environment.

21. As Matthias Varga von Kibéd and Rudolph Matzka (1993) stress, continence should be interpreted on the basis of its etymological relationship to the Latin 'continere', 'to hold together'. Thus, 'distinction is perfect continence' makes clear not only that the origin of the two sides is to be contained in the distinction, but also (and primarily) that the form has no anchoring in any outside reality or foundation – it is the context of itself, it is 'closure'.

22. It is important to stress similarities between *LoF* and lambda-calculus. A lambda domain is a class of objects that can act on one another to form new objects of the same kind. It thus presupposes self-reference or recursivity. Church and Curry (1933) recognized the latter most clearly, and in this respect proved the 'fixed point theorem', saying: 'For every element F in the lambda domain, there is a J in that domain for which $F(J) = J$ '. Louis Kauffman (2001a: 102ff) provides most obvious clues on the recursivity of the universe and mathematics in a comparison of Spencer-Brown's ideas with ideas of Charles Sanders Peirce.

23. I surmise this is the meaning and function of the mysterious ‘unwritten cross’, already introduced in the very beginning of the calculus: ‘Suppose any sn [primal space] to be surrounded by an unwritten cross’ (Spencer-Brown, 1994 [1969]: 7).

24. For a comparison with traditional epistemologies see Christis (2001).

25. This is, I am afraid, one of the main reasons why *LoF* does have a poor reception. Among others, Kuroki Gen perceives the assumedly mystical nature of *LoF* (especially its numerous forewords), and its cult status with the psychedelic generation of the 1960s, as a reason to ignore its insights. Beyond doubt, Spencer-Brown is in large part responsible for further isolating *LoF* from a broader academic public, and that is deplorable.

26. This leads to the question of why Spencer-Brown does not employ a similar view as form as the difference between itself and the medium in which it is written. Peter Fuchs has argued that *LoF* does not need the notion of ‘medium’ as its field of inquiry is mathematics, and as such without heuristical aspirations. As my above considerations on *LoF* show, I am not so sure this is the case. George Spencer-Brown makes mention of the notion of medium in at least two passages (see Schiltz, 2003). Furthermore, he obviously employs the notion of medium in order to be able to show the possibility of self-referential forms (the medium of plane space versus the medium of the torus). Yet, I believe he does not pronounce it in view of his utmost attention for notational matters:

Returning, briefly, to the idea of existential precursors, we see that if we accept their form as endogenous to the less primitive structure identified, in present-day science, with reality, we cannot escape the inference that what is commonly regarded as real consists, in its very presence, merely of tokens or expressions. (Spencer-Brown, 1994 [1969]: 104)

In principle, *LoF* can suffice with its topological notation, as long as we are aware of its intricacies (e.g. the distinction between crosses and markers in Chapter 11).
